Freedreno Update
FOSDEM 2013

Freenode: #freedreno
Web: http://freedreno.github.com/
Motivation: Lack of opensrc gfx on ARM

• Open Source is about freedom
  – If you have the src and the will, you have a way
    • New widget, new feature, new distro...
• For modern UI the GPU becomes more important
  – If you don't have the src, then you are limited by the blob
• Android is dominant because of the blob
  – Gives SoC vendors a single platform to support
  – Doesn't really care that platform drivers work in a clean/sane way or reusability outside of android
  – Either use android or unaccelerated
• As a result → hacks
  – Boot to Gecko using android HALs
  – libhybris – dynamic loader hacks to reuse blobs
  – But will just be all sorts of glue / duct tape
• But lima/mali gave some hope that things can change
History

- **2d – z180**
  - Started working on intercepting/parsing 2d cmds in march 2012
  - Basic EXA (fill/solid/composite) working in Apr
  - After that, mostly sidetracked on 3d
  - Batching working in Oct
  - Still a bit in need of some love and debugging

- **3d – a220**
  - Intercepting and initial parsing 3d cmds in Apr
  - First renders with fdre end of Jun
    - Using hard-coded, pre-compiled shaders
  - Start on shader disassembler in early Jul
  - Shader assembler for fdre and of Jul
  - Gallium driver started Nov
Adreno Overview

- 3d core – a2xx, a3xx
  - Origin: ATI/AMD Imageon
    - Similar heritage as r300/r600
  - Psuedo-TBDR
    - Hidden surface removal
    - Memory bandwidth reduction in common cases
    - GMEM macro-tile: 256KiB or 512KiB vs 16x16 or 32x32
    - Starting with a330, OCMEM (on-chip mem) instead of GMEM...
      seems to be shared w/ other accelerators like video codecs
  - I suspect similar to xbox360 / Xenos
- 2d core – z1xx
  - Origin: bitboys (I think)
  - OpenVG core... but focusing on what is needed for EXA
  - Not really any similarity to 3d core, different CP format, no GMEM, etc
  - Different adreno versions have zero, one, or two 2d cores
Tools of the Trade...

- **libwrap.so** – intercept ioctl's, dump gpu buffers and cmdstream
- **redump** – cmdstream parser / diff-tool for 2d
- **cffdump** – cmdstream parser for 3d
  - Follows gpu ptrs (IB's, vertices, consts)
  - Shader disassembler
  - Some register bitfield and PM4 opc parsing
- **pgmdump**
  - Shader program binaries dumped via GL_OES_get_program_binary extension implemented in blob driver
  - Shader disassembler
  - Used in shader ISA r/e to compare output of similar shaders, to find instruction opcodes, etc
- **fdre**
  - Simple GL-like API
  - an easy way to exercise the GPU
  - Shader assembler
  - Depth/stencil/textures working
  - Used before gallium driver, and now to have simple way to experiment and test theories
Tools of the Trade...

restore-resolve-depth16.txt : restore-resolve-depth24stencil8.txt – Meld

Ln 142, Col 16 INK
3d: Tiling

- Color buffer + Depth + Z must fit in GMEM
  - Side by side
  - 16bit Z or 24bit Z + 8bit stencil (optional)
- Rendering done in passes
  - GMEM is 512KiB on a220, 256KiB on a200
  - Without using hw binning/tiling:
    - Set scissor, IB to buffer w/ draw cmds
  - With hw binning (I think, not implemented yet):
    - Simple vertex shader pass to figure out which vertices in which bin (to avoid running VS many times)
3d: commandstream

- **Command Parser**
  - Same as r300/r600 – PM4 type0/3

- **Registers**
  - Few similar registers (but different offset)
  - Mostly different

- **Opcodes** – different

- **“amd-gpu” kernel driver \o/**
  - Recently found kernel driver from freescale kernel
  - Has pretty much all regs/bitfields as of a200
  - Opcode names/id's but not format
3d: commandstream

IB – indirect branch

- clear/draw cmds
- tile0
- tile1
- tileN

GPU begins executing from here

- Rendering within each tile works like traditional IMR
- The per-tile commands:
  - “restore” (optional) – mem2gmem() – transfer current contents from system memory to GMEM (tile buffer, color + depth/scissor)
  - Setup window-offset and screen scissor
  - IB to clear/draw cmds
  - “resolve” – gmem2mem() – transfer GMEM contents back to system memory
- Notes:
  - Not yet using “hw binning” - looks like that should reduce vertex processing load for vertices not related to the current tile
  - The order of cmdstream building is not the same as order that GPU executes, and restore/resolve steps dirty some state used in clear/draw calls, so some care must be taken
3d: ISA

- Unified shader ISA
- Separation of CF and ALU/FETCH
  - 48bit CF instructions in pairs
    - Control flow instructions reference offset of ALU instructions in 3*dword (96bit)
  - 96bit ALU instructions
    - Co-dispatch of vec4+scalar
uniform sampler2D g_NormalMap;
uniform float foo;
varying vec2 vTexCoord0;

void main()
{
    vec3 vNormal = vec3(2.0, 2.0, 0.0) * texture2D(g_NormalMap, vTexCoord0).xyz;
    vNormal.z = foo * -dot(vNormal, vNormal);
    gl_FragColor = vec4(vNormal, 1.0);
}
Status

- Hardware:
  - So far, just a220/z180
  - Snapdragon S3 (APQ8060, MSM8260, MSM8660)
    - eg. HP touchpad, dragonboard
  - a200/z160 looks like it should be pretty similar, not sure about others
  - nexux-4 with a320 on order, so we shall soon see :-)
- EXA/2d support:
  - Basics work, some bugs
  - Composite blits w/ mask surface not implemented yet
  - Enough registers understood, so just need time to implement
- Gallium/3d support:
  - Basics work, some bugs
  - >50% of glmark2, xbmc, compiz, q3a
    - Still needed
      - cmdstream: MSAA, mipmap textures
      - compiler: loops, optimizing
      - hw binning
